Abstract

The present study was conducted on the testes of six healthy adult Large White Yorkshire pigs. Parenchyma of testes of adult boars was surrounded by a thick fibrous testicular capsule composed of inner tunica vasculosa, middle tunica albuginea, and outer visceral layer of tunica vaginalis. Tunica vasculosa was prominent and characterised by loose connective tissue contained numerous blood vessels. Tunica albuginea was composed of irregular connective tissues made up of collagen, elastin and reticular fibres. Visceral layer of tunica vaginalis was found as outer thin layer of testicular capsule comprised of mesothelium and connective tissue layer. Connective tissue layer was blended with underlying connective tissues of tunica albuginea.

Keywords: Histomorphology, pig, testicular capsule

According to Leena et al. (2004), only a few states in India are successful in modern pig farming, with Kerala being the most notable. Availability of plenty of swill and food habits, makes pig farming a beneficial livestock sector in Kerala (Kannan et al., 2008). Testes are the primary reproductive and endocrine organs or gonads in the male, responsible for the production of functional spermatozoa, secretion of hormones and factors that involve all aspects of sexual development and reproductive functions. Studies and literature pertaining to histomorphology of testes of pigs are scanty, hence the study was undertaken.
Materials and methods

The present study was conducted on the testes of six healthy adult Large White Yorkshire (LWY) pigs slaughtered at the Meat Technology Unit, Kerala Veterinary and Animal Sciences University. Tissue samples of testes were collected from cranial, middle and caudal parts of the testes and fixed in 10% neutral buffered formalin for 48 hours. Paraffin blocks were made by alcohol-xylene sequence (Luna, 1968). The sections were cut at 5μ thickness and stained by Haematoxylin and eosin (H&E) staining for general cytoarchitectural studies (Luna, 1968). Special staining methods like Van Gieson’s staining for collagen fibres (Luna, 1968), Masson’s trichrome staining for muscles and collagen fibres (Luna, 1968), Verhoeff’s staining (Singh and Sulochana, 1996) for elastic fibres, Gomori’s method for reticular fibres (Luna, 1968) and Phosphotungstic acid haematoxylin (PTAH) staining for muscles (Luna, 1968) were also employed.

Results and discussion

Testicles of crossbred Large White Yorkshire boars were found white in colour, large, regularly elliptical shaped, placed at the perineal region and directed backwards and upwards forming a prominent landmark about 6-8 cm below the anus. Parenchyma of the testes of adult boars was surrounded by a thick fibrous testicular capsule and was characterised by regularly arranged dense connective tissue made up of three layers viz., inner tunica vasculosa, middle tunica albuginea and outer visceral layer of tunica vaginalis (Fig. 1). These findings were similar to the reports of Ahmed and Sinowatz (2005) in bull, Dhyana et al. (2016), Singh et al. (2019) and Singh et al. (2020) in adult boar and Khan et al. (2019) in buck.

The innermost, highly vascularised and prominent tunica vasculosa, which was contained in the deeper portion of the capsule was distinguished by dense regular connective tissue (Fig. 1). These observations are in accordance with the reports of Shukla et al. (2013) in stallion and Dhyana et al. (2016), Singh et al. (2019), Singh et al. (2020) in adult boar. Tunica albuginea, the middle layer of testicular capsule had dense regular connective tissue which was composed of collagen (Fig. 2), elastic (Fig. 2) and reticular fibres (Fig. 3) along with fibroblasts, smooth muscle fibres (Fig. 4) and a few blood vessels. These observations are similar to the reports given by Shukla et al. (2013) in stallion, Dhyana et al. (2016) in domestic pig of Hyderabad, Singh et al. (2019) in local pig (Zovawk) of Mizoram and Singh et al. (2020) in LWY boar and contrary to the findings of Trautmann and Fiebiger (1952), who discovered tunica vasculosa in the centre of the testicular capsule in both stallion and boar.

Visceral layer of tunica vaginalis was found as a thin outer layer of testicular capsule comprised of outermost mesothelium and underlying connective tissue layer (Fig. 1). Connective tissue layer was formed of collagen fibres and a few elastic and reticular fibres that blended with underlying connective tissues of tunica albuginea as observed as Dhyana et al. (2016) in pigs. Due to this blending, visceral layer of tunica vaginalis could not be clearly delineated from the outer fibrous layer of testicular capsule.

Conclusion

The results presented on the histology of testicular capsule of boars are those of normal, adult, sexually active ones. Parenchyma of the testes of adult boars was surrounded by a thick fibrous testicular capsule and was characterised by regularly arranged dense connective made up of three layers viz., inner tunica vasculosa, middle tunica albuginea and outer visceral...

layer of tunica vaginalis. Tunica albuginea was the middle layer of testicular capsule which was composed of collagen, elastic and reticular fibres along with fibroblasts, smooth muscle fibres and a few blood vessels. The presence of smooth muscle cells in the capsule could be attributed to the transport of spermatozoa whereas the collagen fibres and fibroblasts for the mechanical support.
