Abstract

The rearing of chicken in India has undergone a drastic change from backyard production to commercial intensive farming. This has led to the use of antibiotics in therapy, metaphylaxis and as growth promoters. *Escherichia coli* are commensals that inhabit the gut of man and animals. The detection of virulent pathotypes of *E. coli* in chicken is a huge threat to human health. The present study assessed 200 retail chicken sold in central Kerala for the presence of virulent *E. coli* and studied the tetracycline susceptibility followed by detection of tetA and tetB gene. *E. coli* was detected in 64 per cent of the samples. The virulence genes, eaeA and aggR were detected in 52.2 and 3.9 per cent of the *E. coli* isolates, respectively. Tetracycline resistance by antibiotic susceptibility testing (ABST) was found in 30.84 per cent of the virulent isolates. The tetracycline efflux pump protein coding genes, tetA and tetB were detected in 56.67 and 25 per cent, respectively. The detection of drug resistant bacteria is a threat to public health as tetracycline is classified as a highly important antibiotic in human medicine.

Keywords: *E. coli*, tetracycline resistance, tetA, tetB

Chicken is a cheap source of animal protein and it is relished because of its versatility in cuisine and because no religious or cultural taboos are associated with its consumption (Khara et al., 2020). In order to meet the growing demand, chicken rearing in India has undergone a paradigm shift from mere backyard rearing to a commercial enterprise. In order to cater to the boost in demand, antibiotics are being rampantly used in metaphylaxis, therapy and also in feed as growth promoters. Promiscuous use of antibiotics leads to increase in the incidence of drug resistant bacteria.

Escherichia coli are commensals which reside in the gut of poultry. Improper dressing practices leads to the contamination of chicken with faecal matter thereby contributing to the presence of E. coli in the meat. Most of the strains of E. coli are usually harmless but a few strains are highly pathogenic. Escherichia coli strains that cause enteric disease in their hosts are called diarrhoeagenic E. coli (DEC) and their pathogenesis is associated with a number of virulence attributes which varies with the pathotypes (Xia et al., 2010).

Intimin is a 94-kDa outer membrane protein encoded by the eaeA gene which is required for the intimate attachment of bacteria with the enterocyte membranes (Trabulsi et al., 2002). The aggR gene is a transcriptional regulator which regulates the expression of aggregative adherence fimbriae in enteroaggregative E. coli. Penetration into the epithelial cells and dissemination from cell to cell in enteroinvasive E. coli are mediated by an invasion-associated locus (iai), located on a plasmid and the invasion plasmid antigen H (ipaH) genes present in both chromosome and plasmid (Farajzadeh-Sheikh et al., 2020). These organisms are notorious for their role in the transmission of antimicrobial resistance (AMR) as faecal microbes acts as reservoirs of AMR (Purohit et al., 2019). These organisms are notorious for their role in the transmission of antimicrobial resistance (AMR) as faecal microbes acts as reservoirs of AMR (Purohit et al., 2019).

Tetracyclines are broad spectrum antibiotic and are popular because of their efficacy and low cost (Zibandeh et al., 2016). They are used in therapy and also as growth promoters as they have been proven to increase the weight of the birds. The first generation tetracyclines such as oxytetracycline and chlortetracycline have been used as growth promoters for decades. Second generation tetracyclines such as minocycline and doxycycline have been used in metaphylaxis and therapy. The indiscriminate use of tetracycline has led to the selection of tetracycline resistant bacteria (Koo and Woo, 2011). The present study was envisaged with the objective of studying the prevalence of E. coli in retail chicken sold in central Kerala, occurrence of virulence genes, assess the susceptibility of the isolates to tetracycline and finally to check if the isolates harbour the efflux pump encoding genes, tetA and tetB.

Materials and methods

Hundred retail chicken samples each were collected from two central districts of Kerala viz., Thrissur and Ernakulam. Each sample of chicken consisted of 250g and included portions of neck, breast and thigh (Bhandari et al., 2013). The chicken samples were brought to the laboratory immediately under refrigeration conditions. The isolation of E. coli was done according to the procedure of Meng et al. (2001). Briefly, from each pooled composite chicken meat sample, a 25 g portion was aseptically removed using sterile scissors and forceps. The sample was transferred to 225 mL volumes of buffered peptone water (Difco) in sterile stomacher bags, processed for 120 s. in a stomacher (Smasher, AES, France) and incubated at 37°C for 18 h. Following incubation, a loopful was transferred to Mac Conkey agar and incubated at 37°C for 24 h. At the end of incubation, lactose fermenting bright pink coloured colonies surrounded by bile precipitate was selected based on morphology and subjected to biochemical tests as described by Barrow and Feltham (1993). The isolates confirmed as E. coli by culture were subjected to snap chill method for the extraction of DNA (Swetha et al., 2015).

The DNA was subjected to PCR for the detection of virulence genes, eaeA, aggR and ipaH using the primers as shown in Table 1. Multiplex PCR was performed in a final volume of 25 µL reaction mixture using 3 µL of extracted DNA as template. The cyclic conditions were standardised in the study: initial denaturation at 95°C for 5 min. followed by 35 cycles of denaturation at 94°C for 1 min, annealing at 58°C for 1 min, extension at 72°C at 40 s followed by final extension at 72°C for 10 min.

All the isolates that were positive for virulence genes were subjected to antibiotic susceptibility test against tetracycline using standard disc diffusion method (Skoczková et al., 2015) using tetracycline disc (HiMedia)
with a concentration of 30 µg. The isolates that showed resistance to tetracycline by phenotypic method were subjected to two separate PCR for the detection of tetA and tetB genes. The reaction mixture included, 2.5 µL of 10X PCR buffer, 2 µL of 25mM MgCl₂, 0.50 µL of Taq DNA polymerase (5 Units/µL), 0.50 µL of dNTP Mix (10mM), 10 pmoles/µL each of forward and reverse primers of tetA and tetB and nuclease free water made up to 25 µL total volume. The primers used for the detection of tetA and tetB are shown in Table 2.

The cyclic condition of PCR for tetA gene included an initial denaturation at 95 °C for 5 min, followed by 35 cycles of denaturation at 94°C for 45 s, annealing at 59.5°C for 1 min, extension at 72°C for 1 min followed by final extension at 72°C for 5 min. The cyclic conditions followed for tetB gene was as follows; initial denaturation at 95°C for 5 min, followed by 35 cycles of denaturation at 94°C for 45 s, annealing at 66°C for 30 s, extension at 72°C for 45 s which was followed by final extension at 72°C for 5 min.

Results and discussion

The prevalence of *E. coli* by culture was found to be 67 and 61 per cent from Thrissur and Ernakulam, respectively, with an overall prevalence of the organism from central Kerala being 64 per cent. The results are similar to studies in Bangladesh, where a prevalence of 63.5 per cent was reported (Rahman et al., 2020). However, a higher prevalence of 87.5 per cent was reported by Eyi and Arslan (2012) from Turkey and an occurrence of 76.5 per cent was reported from coacal swabs of chicken from Kollam district of Kerala (Afsal et al., 2021). A study from Wayanad in Kerala reported the occurrence of *E. coli* in 36.11 per cent of cloacal swabs from broiler chicken which is much lower than the present study (Sathya et al., 2019). There was no significant statistical difference (p≥0.01) in the prevalence of the organism between the two districts.

Of the three virulence genes, only eaeA and aggR were detected. None of the isolates harboured ipaH gene. The amplicons were obtained at 209 and 254bp for eaeA and aggR respectively (Fig. 1). The eaeA gene was detected in 86.57 and 77.05 from Thrissur and Ernakulam, respectively. Totally, the gene was detected in 81.81 per cent of the isolates. This accounts for the presence of eaeA in 52.2 per cent of the retail chicken tested. This is in accordance with the study by Wang et al. (2017), where eaeA was detected in 50 per cent of the chicken tested in Japan. The aggR gene was detected from 2.99 and 4.92 per cent of the *E. coli* isolates from Thrissur and Ernakulam. Overall, aggR was detected in 3.9 per cent of the isolates. However, a higher per cent of occurrence of aggR (24.44) was detected by Kagambega et al. (2012) from West Africa. A study from Mumbai in India by Godambe et al. (2017) could not detect either eaeA or aggR from any of the *E. coli* isolates from chicken.

Of the 107 isolates of virulent *E. coli* obtained from central Kerala, resistance to tetracycline was detected in 33 isolates (30.84 per cent), whereas intermediate susceptibility was noted in 27 isolates (25.23 per cent). The results are in accordance with that of Skočková et al. (2015), from Czech Republic, where the level of resistance to tetracycline was reported to be 34.5 per cent. However, studies by Ingram et al. (2013), Chakravarty et al. (2015) and Bhardwaj et al. (2021) from Western Australia and different parts of India, respectively reported cent per cent resistance to tetracycline. Both the tetracycline resistant and intermediate susceptible isolates were subjected to PCR for the detection of tetA and tetB genes. The amplicons for tetA and tetB were obtained at 209 and 169 bp, respectively (Fig. 2). The district-wise distribution of the tetracycline resistance genes tetA and tetB is shown in Table 3. The tetA gene was detected in 75.76 per cent and 33.33 per cent of the resistant and intermediate susceptible isolates, respectively. Whereas, tetB was detected in 39.39 and 7.40 per cent of resistant and intermediate isolates, respectively. Both tetA and tetB together were detected in 30.30 per cent of resistant and 3.70 per cent of intermediate susceptible isolates. Overall tetA was detected in 56.67 per cent which is in accordance with a study in Norway where tetA was detected in 55 per cent of resistant isolates (Sunde and Norström, 2006). Nevertheless, a higher level of detection of 89.5 and 74 per cent was reported by Van et al. (2008) and Bhardwaj

et al. (2021), respectively. The *tetB* gene was detected in 25 per cent of the tetracycline resistant and intermediary isolates. However a study in Korea (Koo and Woo, 2011) reported a higher occurrence of *tetB* gene (41.3 per cent). Only 13 per cent of the *E. coli* isolates obtained from chicken in Karnataka, India harboured *tetB* gene (Bhardwaj *et al.*, 2021). The combined presence of both *tetA* and *tetB* was detected in 18.33 per cent of the isolates. This is contrary to a study in Vietnam, where both the genes were present at the same level of 89.5 per cent (Van *et al.*, 2008).

Till date three resistance mechanisms to tetracycline have been recorded. The efflux pump proteins are one of the best studied mechanisms. These efflux pumps push the drug out of the bacterial cell using an energy dependent process. Twenty three different efflux pump genes are identified so far of which the most common ones being *tetA* and *tetB*. The *tetA* codes for resistance to tetracycline but not minocycline. On the other hand, *tetB* codes for resistance to both tetracycline and minocycline. Another mechanism of tetracycline resistance is by ribosomal protection coded by 11 genes. Yet another mechanism of resistance is by enzymatic inactivation of tetracycline by three genes (Roberts and Schwarz, 2017). The present study targeted the two most common genes coding for the efflux pump. Thus, not all the isolates that showed resistance to tetracycline by phenotypic methods were confirmed with the molecular tools.

The study highlights the presence of tetracycline resistant *E. coli* among healthy broiler chicken sold in central Kerala. The detection of drug resistant bacteria is a threat to public health as tetracycline especially chlorotetracycline is classified as a highly important antibiotic to be reserved for use in humans and is listed as one of the critically important antibiotic published by the World Health Organisation (WHO, 2019). In order to
To curtail the spread of antimicrobial resistance, a multisectoral and multifaceted one health approach must be adopted in addition to antibiotic stewardship, infection control and strict regulations on the use of antimicrobials.

Conclusion

Tetracycline is listed as an important antibiotic, because of its significance in human medicine. Confirmation of resistance against tetracycline in E. coli isolated from chicken is a great threat to public health. Furthermore, the organism is also known for the transfer of drug resistance genes not only within the same genera but also among other bacterial genera which again complicates the issue. Hence the results of the present study emphasises the need to use tetracycline with caution in poultry production so as to curb the spread of AMR through the food chain.
